

Robotics for Scalable Biodiversity Discovery

- Large-scale biological discovery still depends on **manual human labor**.
- Specimen picking, plate movement, imaging, sample prep, and metadata tracking become **bottlenecks**.
- We are using robotics to automate these repetitive physical steps.
- **Goal:** turn small-organism discovery into scalable biological infrastructure.

- Robotics can lower the cost of sequencing and imaging small organisms.
- Target cost: \$0.25 per individual.
- If achieved, biodiversity workflows can scale far beyond manual throughput.

\$0.25 per individual

Results and Impact

- Enables larger-scale organism imaging and DNA sequencing.
- Supports biodiversity discovery at a scale not practical with manual workflows.
- Creates tools to ground-truth biological diversity surveys at scale.
- Helps governments, nonprofits, and researchers monitor environmental change.

Next Steps

- Implement **downstream automation**, including liquid handling.
- Connect workflows to high-throughput **DNA sequencing**.
- Build an **agentified feedback loop** to identify useful discovery directions.
- Use that loop to prioritize candidates for **new species discovery**.
